## Paper Overview

This paper investigates spin-dependent (SD) scattering of sub-GeV dark matter (DM) off electrons in target materials, extending the DarkELF framework to handle spin-dependent interactions. The authors consider various DM models (e.g., dark photon with axial coupling, scalar mediators), compute SD scattering rates in semiconductor (Si, Ge) and molecular targets, derive exclusion limits from existing experimental data (SENSEI, DAMIC, XENON, etc.), and project sensitivity for future experiments. The calculations use DFT-derived electronic structure (wave functions and response functions).

## Detailed Workflow

### Phase 1: Theoretical Framework

#### 1.1 Implement DM-electron scattering rate formulas.

- Differential scattering rate  $dR/dE$  for spin-dependent interactions.
- DM form factors for different mediator models (heavy/light mediator limits).
- DM velocity distribution (Standard Halo Model, Maxwell-Boltzmann with escape velocity).

#### 1.2 Define target material response functions.

- Crystal form factor  $|f_{\text{crystal}}(q, \omega)|^2$  from DFT band structure.
- Spin-dependent generalization of the response function.

### Phase 2: Electronic Structure Inputs

#### 2.1 Obtain DFT-computed response functions.

- Use DarkELF's built-in data for Si, Ge (from Quantum ESPRESSO DFT calculations).
- Or compute from scratch using DFT + Wannier interpolation.

#### 2.2 Compute the dynamic structure factor $S(q, \omega)$ and its spin-dependent analog.

### Phase 3: Rate Calculations

#### 3.1 Compute scattering rates for each DM model and target material.

#### 3.2 Sweep DM mass $m_\chi$ over the sub-GeV range (1 MeV – 1 GeV).

#### 3.3 Compute event rates (counts/kg/year) as a function of cross-section $\bar{\sigma}_e$ .

### Phase 4: Experimental Constraints

#### 4.1 Apply experimental exposure and efficiency.

- SENSEI, DAMIC, CDEX, XENON10/1T data.
- Apply energy thresholds, acceptance efficiencies, exposure.

#### 4.2 Derive 90% C.L. exclusion limits on $\bar{\sigma}_e$ vs. $m_\chi$ .

#### 4.3 Compute projected sensitivities for future experiments.

## Phase 5: Validation

- 5.1 Reproduce exclusion limit plots from the paper.
- 5.2 Reproduce rate comparison between SI and SD scattering.
- 5.3 Verify against known DarkELF benchmarks for SI case.

## Datasets

## Hardware Requirements

- Rate calculations with DarkELF: any laptop (seconds to minutes per mass point).
- DFT calculations (if needed): HPC cluster,  $\geq 32$  cores,  $\geq 64$  GB RAM.
